

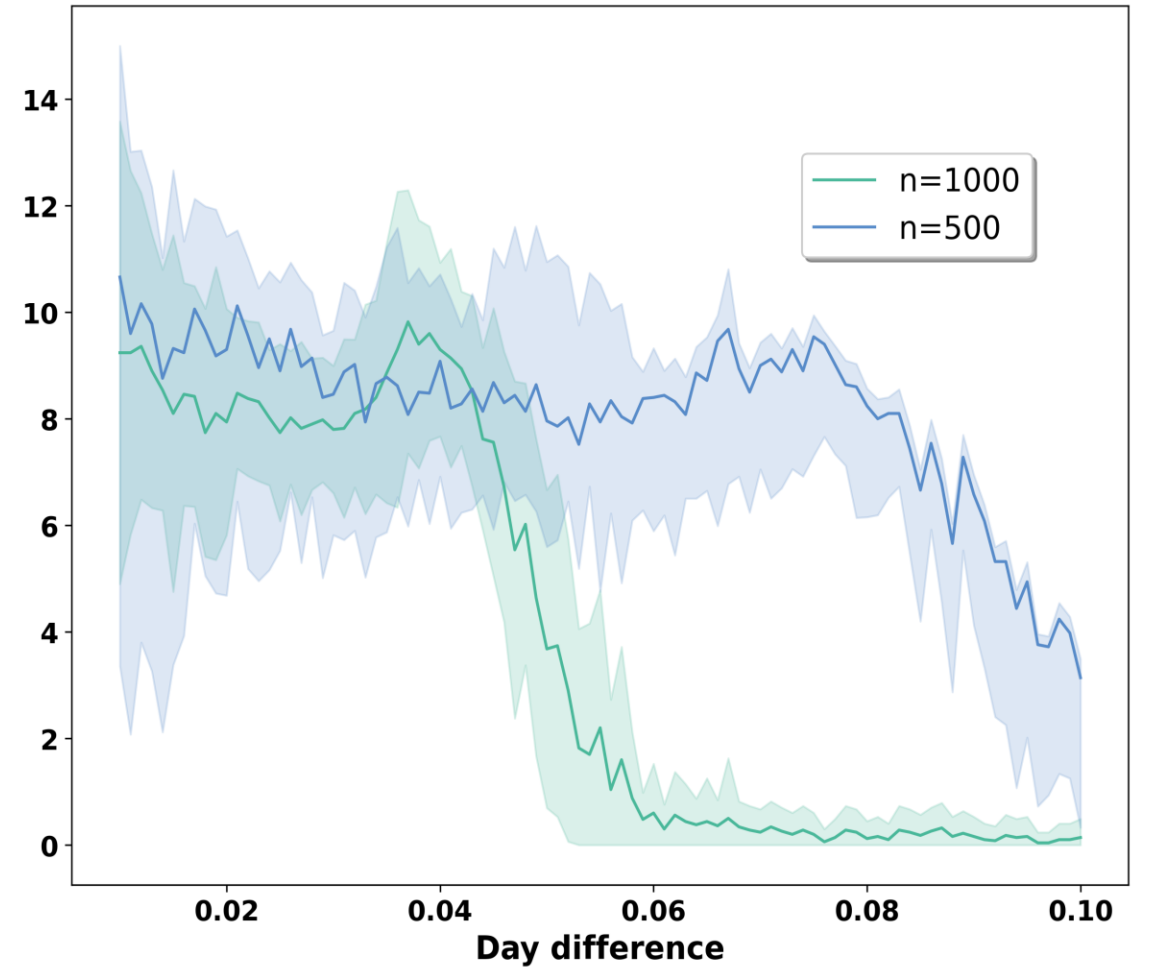

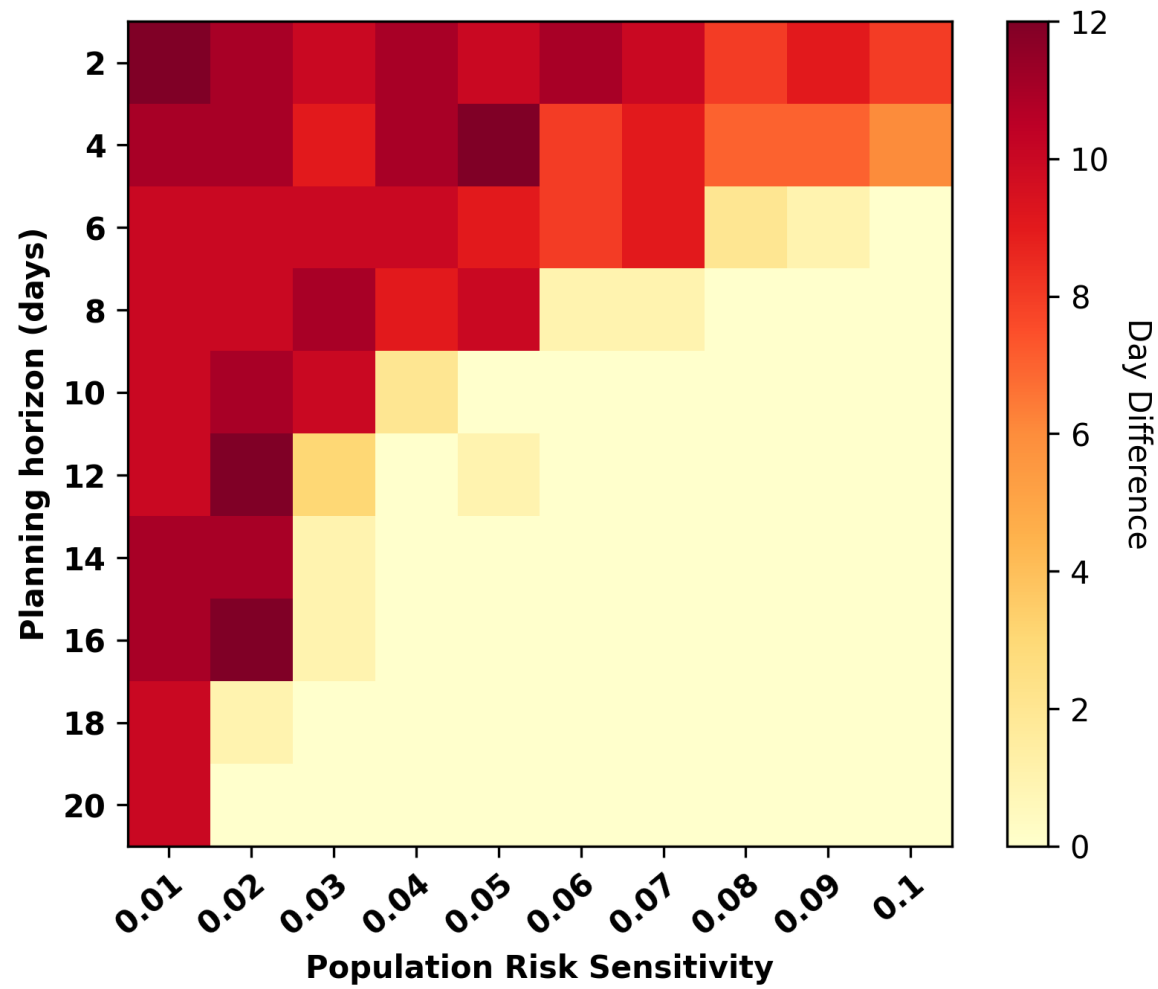

Fig. 3. The left panel shows the average day difference between the maximum edge reductions at local and global levels, for different values of (ν, τ) . For larger values of these parameters, the effort reduction at the local level synchronizes with the response at the global level. Simulations were performed on an Erdős–Rényi base network with $n = 500$ nodes and a probability of edge creation of $p = 0.05$. The right panel shows that a similar effect occurs when the network connectivity increases.
